

1. Business Problem

1.1 Problem Description

Netflix is all about connecting people to the movies they love. To help customers find those movies, they developed world-class movie recommendation system: CinematchSM. Its job is to predict whether someone will enjoy a movie based on how much they liked or disliked other movies. Netflix use those predictions to make personal movie recommendations based on each customer's unique tastes. And while **Cinematch** is doing pretty well, it can always be made better.

Now there are a lot of interesting alternative approaches to how Cinematch works that netflix haven't tried. Some are described in the literature, some aren't. We're curious whether any of these can beat Cinematch by making better predictions. Because, frankly, if there is a much better approach it could make a big difference to our customers and our business.

1.2 Problem Statement

Netflix provided a lot of anonymous rating data, and a prediction accuracy bar that is 10% better than what Cinematch can do on the same training data set. (Accuracy is a measurement of how closely predicted ratings of movies match subsequent actual ratings.)

1.4 Real world/Business Objectives and constraints

Objectives:

1. Predict the rating that a user would give to a movie that he has not yet rated.
2. Minimize the difference between predicted and actual rating (RMSE and MAPE)

Constraints:

1. Some form of interpretability.

2. Machine Learning Problem

2.1 Data

2.1.1 Data Overview

Get the data from : <https://www.kaggle.com/netflix-inc/netflix-prize-data/data>

Data files :

- combined_data_1.txt
- combined_data_2.txt
- combined_data_3.txt
- combined_data_4.txt
- movie_titles.csv

The first line of each file [combined_data_1.txt, combined_data_2.txt, combined_data_3.txt, combined_data_4.txt] contains the movie id followed by a colon. Each subsequent line in the file corresponds to a rating from a customer and its date in the following format:

CustomerID,Rating,Date

MovieIDs range from 1 to 17770 sequentially.

CustomerIDs range from 1 to 2649429, with gaps. There are 480189 users.

Ratings are on a five star (integral) scale from 1 to 5.

Dates have the format YYYY-MM-DD.

2.2 Mapping the real world problem to a Machine Learning Problem

2.2.1 Type of Machine Learning Problem

For a given movie and user we need to predict the rating would be given by him/her to the movie.

The given problem is a Recommendation problem

It can also be seen as a Regression problem

2.2.2 Performance metric

- Mean Absolute Percentage Error: https://en.wikipedia.org/wiki/Mean_absolute_percentage_error
- Root Mean Square Error: https://en.wikipedia.org/wiki/Root-mean-square_deviation

2.2.3 Machine Learning Objective and Constraints

1. Minimize RMSE.
2. Try to provide some interpretability.

plt.xlabel('Movie')
plt.ylabel('No of Users who rated a movie')
ax.set_xticklabels([])

plt.show()

- It is very skewed.. just like number of ratings given per user.

- There are some movies (which are very popular) which are rated by huge number of users.
- But most of the movies (like 90%) got some hundreds of ratings.

3.4.1.2 Trying with reduced dimensions (Using TruncatedSVD for dimensionality reduction of user vector)

- We have **405,041 users** in our training set and computing similarities between them..(**17K dimensional vector**..) is time consuming..
- From above plot, It took roughly **8.88 sec** for computing similar users for **one user**
- We have **405,041 users** with us in training set.
- $405041 \times 8.88 = 3596764.08\text{sec} = 59946.068\text{ min}$
 - Even if we run on 4 cores parallelly (a typical system now a days), It will still take almost **10 and 1/2 days**.

IDEA: Instead, we will try to reduce the dimensions using SVD, so that it **might** speed up the process...

In [0]:

```
from datetime import datetime
from sklearn.decomposition import TruncatedSVD

start = datetime.now()

# initialize the algorithm with some parameters..
# All of them are default except n_components. n_iter is for Randomized SVD solver.

Here,

- $\sum \rightarrow (\text{netflix_svd.singular_values_})$
- $\bigvee^T \rightarrow (\text{netflix_svd.components_})$
- \bigcup is not returned. instead **Projection_of_X** onto the new vectorspace is returned.
- It uses **randomized svd** internally, which returns **All 3 of them separately**. Use that instead..

```

I think 500 dimensions is good enough

- By just taking (20 to 30) latent factors, explained variance that we could get is 20 %.
- To take it to 60%, we have to take **almost 400 latent factors**. It is not fare.
- It basically is the **gain of variance explained**, if we **add one additional latent factor to it**.
- By adding one by one latent factor too it, the **gain in explained variance** with that addition is decreasing. (Obviously, because they are sorted that way).
- **LHS Graph:**
 - **x** --- (No of latent factors),
 - **y** --- (The variance explained by taking x latent factors)
- **More decrease in the line (RHS graph) :**
 - We are getting more explained variance than before.
- **Less decrease in that line (RHS graph) :**
 - We are not getting benifitted from adding latent factor furthur. This is what is shown in the plots.
- **RHS Graph:**
 - **x** --- (No of latent factors),
 - **y** --- (Gain n Expl_Var by taking one additional latent factor)

- **Why did this happen...??**
 - Just think about it. It's not that difficult.

(sparse & dense.....get it ??)

Is there any other way to compute user user similarity..??

-An alternative is to compute similar users for a particular user, whenever required (ie., **Run time**)

- We maintain a binary Vector for users, which tells us whether we already computed or not..
- *****If not***** :
 - Compute top (let's just say, 1000) most similar users for this given user, and add this to our datastructure, so that we can just access it(similar users) without recomputing it again.
- *****If It is already Computed*****:
 - Just get it directly from our datastructure, which has that information.
 - In production time, We might have to recompute similarities, if it is computed a long time ago. Because user preferences changes over time. If we could maintain some kind of Timer, which when expires, we have to update it (recompute it).
- *****Which datastructure to use*****
 - It is purely implementation dependant.
 - One simple method is to maintain a ****Dictionary Of Dictionaries****.
 - ****key** : ****_userid_**
 - **__value__** : **_Again a dictionary_**
 - **__key__** : **_Similar User_**
 - **__value__** : **_Similarity Value_**

4.3.2 Transforming data for Surprise models

In [28]:

```
from surprise import Reader, Dataset
```

4.3.2.1 Transforming train data

- We can't give raw data (movie, user, rating) to train the model in Surprise library.
- They have a saperate format for TRAIN and TEST data, which will be useful for training the models like SVD, KNNBaseLineOnly....etc...,in Surprise.
- We can form the trainset from a file, or from a Pandas DataFrame.
http://surprise.readthedocs.io/en/stable/getting_started.html#load-dom-dataframe-py

In [29]:

```
# It is to specify how to read the dataframe.
# for our dataframe, we don't have to specify anything extra..
reader = Reader(rating_scale=(1,5))

# create the traindata from the dataframe...
train_data = Dataset.load_from_df(reg_train_25k[['user', 'movie', 'rating']], reader)

# build the trainset from traindata.. It is of dataset format from surprise library..
trainset = train_data.build_full_trainset()
```

4.3.2.2 Transforming test data

- Testset is just a list of (user, movie, rating) tuples. (Order in the tuple is impotant)

In [30]:

```
testset = list(zip(reg_test_5k.user.values, reg_test_5k.movie.values, reg_test_5k.rating.values))
testset[:3]
```

```
Out[30]:
```

```
[(98579, 71, 4), (875956, 71, 4), (1772930, 71, 5)]
```

4.4 Applying Machine Learning models

- Global dictionary that stores rmse and mape for all the models....
 - It stores the metrics in a dictionary of dictionaries

```
keys : model names(string)
```

```
value: dict(key : metric, value : value )
```

```
In [31]:
```

```
models_evaluation_train = dict()
models_evaluation_test = dict()

- **predicted Rating : (based on User-User similarity)**

$$\hat{r}_{ui} = b_{ui} + \frac{\sum_{v \in N^k_i(u)} \text{sim}(u, v) \cdot (r_{vi} - b_{vi})}{\sum_{v \in N^k_i(u)} \text{sim}(u, v)}$$

- b_{ui} - Baseline prediction of (user, movie) rating
- $N^k_i(u)$ - Set of **K** similar users (neighbours) of **user (u)** who rated **movie(i)**
- $\text{sim}(u, v)$ - **Similarity** between users **u** and **v**
 - Generally, it will be cosine similarity or Pearson correlation coefficient.
 - But we use **shrunk Pearson-baseline correlation coefficient**, which is based on the pearsonBaseline similarity (we take base line predictions instead of mean rating of user/item)

- **Predicted rating (based on Item Item similarity):**
$$\hat{r}_{uj} = b_{uj} + \frac{\sum_{i \in N^k_u(j)} \text{sim}(i, j) \cdot (r_{ui} - b_{ui})}{\sum_{i \in N^k_u(j)} \text{sim}(i, j)}$$

- **Notations follows same as above (user user based predicted rating)**

Conclusions

1. We have used 25k users and 3k movies for Train data.
2. We used max_depth and n_estimators as best hyperparameters
3. After doing hyperparameter tuning, RMSE values of all models changed even with best values for hyperparameters.
